

TASK 1

1. Review:

Patient details- Female, 45 yrs

Symptoms- Rash, itching, nausea and dizziness

Medication history- Amoxicillin, started 5 days ago
Paracetamol, as needed

2. Analyze:

- a) **Is there a temporal relationship?** Yes. The symptoms appeared after 3 days after starting Amoxicillin.
- b) **Is the reaction drug-related?** Very likely. Rash and itching are often signs of allergic/hypersensitivity reaction. Nausea and dizziness are known side effects of Amoxicillin.
- c) **What is the suspected drug?** Prime suspected drug is Amoxicillin because:
 - Symptoms started 3 days after taking the drug
 - Rash and itching are classic symptoms for any Penicillin-class hypersensitivity
 - Paracetamol seems unlikely as it was taken when needed and can rarely cause such combination of symptoms
- d) **Causality Assessment (WHO-UMC Scale)**
 - **Plausible time relationship?** Yes
 - **Known ADR to the drug?** Yes
 - **Cannot be explained by disease or other drugs?** Unlikely. Paracetamol rarely causes the given combination of symptoms. Medical history did not mention any underlying disease.
 - **Dechallenge information?** No. From the timeline, symptoms are persisting on Day 0. No mention of Amoxicillin being withdrawn.
 - **Rechallenge information?** No.

3. Identify: The symptoms are drug-related and the suspected drug is Amoxicillin.
